Report #1

Identifying the project

Analyzing needs

In order to better understand what we wanted to do, we decided to focus on three main aspects regarding the main guidline “Living better with AI”. We first approached the problems we and the people we know usually use the AI for, trying to underline if the problem could be considered already solved, not solved at all or partially solved, meaning that the use of AI could be further improved. Our second brain-storming (which was actually partially parallel to the first one), aimed to better define the possible users of AI, having in mind why they use or not use AI; finally we tried to explore how we could improve the found problems introducing the implementation of LLMs or upgrading the experience with existing ones.

After the initial process, we selected five main possibilities which dealt with travelling, eccessive use of technological devices, ambiental problems, concerns about the use of AI in mechanical and architectural projects and the ambiental footprint of AI use:

1. The first idea regarded the planning of trips, since the current LLM models mainly propose fixed packages, using the data available often coming from trip agencies, resulting in general plans and not tailored experiences. The pros included the possibility of a highly customizable interface while the cons included a too broad target.
2. The second idea focused on a wide spreaded problem: the excessive use of technological devices (mainly smartphones), aiming to implement a pseudo-psychological chatbot, with which the user could better understand and reflect on its smartphone usage. It would use already available data coming from the already existing function “Usage analysis”, implemented on all modern smartphones. The pros included a very interesting theme, which explored a modern problem while the cons saw the delicacy of the sublect among them.
3. The third idea was basically an implementation of AI models to support the recognition of ambiental problems, mainly in rural contexts, but was later discarded due to the lack of interfaces possibilities. Another interesting point was that AI is not commonly used in farms and similar contexts due to difficulties in internet connections, this representing a challenge the idea would have faced both as a possibilities and as a problem.
4. The fourth idea explored the deskilling problem generated by the “automatic” use of AI during mechanical and architectural projects (e.g. buildings or mechanical parts). Using the AI answers without knowledge and understanding the rules of the subject can cause future lack of skills, hence constituing an interesting problem to solve regarding the future of students like us. However, the concept does not only

apply to educational ambients, but also to possible self learners. The problems we may face include the difficulty to run physic simulations, but the originality of the idea captured us.

5. The last idea proposed to make the resource impact of the increasing use of AI chatbots, but its main problem was the low “scalability” of the project, risking to just become a feature on already existent chatbots.

After proposing two of these ideas, we decided to follow the advices we received and follow the development of the fourth project.
